5.3 Compute (1/10)

Preprocessor
Input
Compute
Output

- Computation is through **function**
 - So far, we have used one function: **int main(void)**
main() function: where execution of program begins
- A **function body** has two parts
 - **Declarations statements**: tell compiler what type of memory cells needed
 - **Executable statements**: describe the processing on the memory cells

```
int main(void) {  
    /* declaration statements */  
    /* executable statements */  
    return 0;  
}
```

Python

```
def main():  
    # statements  
    return 0  
if __name__ == "__main__":  
    main()
```

5.3 Compute (2/10)

Preprocessor
Input
Compute
Output

- **Declaration Statements:** To declare use of variables

`int count, value;`

Data type Names of variables

- **User-defined Identifier**

- Name of a variable or function
- May consist of letters (a-z, A-Z), digits (0-9) and underscores (_), but MUST NOT begin with a digit
- Case sensitive, i.e. **count** and **Count** are two distinct identifiers
- Guideline: Usually should begin with lowercase letter
- Must not be reserved words (next slide)
- Should avoid standard identifiers (next slide)
- Eg: *Valid identifiers:*

`maxEntries, _X123, this_IS_a_long_name`

Invalid:

`1Letter, double, return, joe's, ice cream, T*S`

5.3 Compute (3/10)

Preprocessor
Input
Compute
Output

- **Reserved words (or keywords)**
 - Have special meaning in C
 - Eg: **int**, **void**, **double**, **return**
 - Complete list: <http://c.ihypress.ca/reserved.html>
 - Cannot be used for user-defined identifiers (names of variables or functions)
- **Standard identifiers**
 - Names of common functions, such as **printf**, **scanf**
 - Avoid naming your variables/functions with the same name of built-in functions you intend to use

5.3 Compute (4/10)

Preprocessor
Input
Compute
Output

- Executable statements
 - I/O statements (eg: `printf`, `scanf`)
 - Computational and assignment statements
- Assignment statements
 - Store a value or a computational result in a variable
 - (Note: '=' means '**assign value on its right to the variable on its left**'; it does NOT mean equality)
 - Left side of '=' is called **lvalue**

Eg: `kms = KMS_PER_MILE * miles;`

5.3 Compute (5/10)

Eg: `sum = sum + item;`

Before assignment

Preprocessor
Input
Compute
Output

- Note: **lvalue** must be assignable

- Examples of invalid assignment (result in compilation error “**lvalue required as left operand of assignment**”):
 - `32 = a;` // ‘32’ is not a variable
 - `a + b = c;` // ‘a + b’ is an expression, not variable
- Assignment can be cascaded, with associativity from **right to left**:
 - `a = b = c = 3 + 6;` // 9 assigned to variables `c`, `b` and `a`
 - The above is equivalent to: `a = (b = (c = 3 + 6));`
which is also equivalent to:

```

c = 3 + 6;
b = c;
a = b;
  
```

Python

Can write: `a = b = c = 3 + 6`
CANNOT: `a = 5 + (b = 3)`

5.3 Compute (6/10)

Preprocessor
Input
Compute
Output

□ Side effect:

- An assignment statement does not just assigns, it also has the side effect of returning the value of its right-hand side expression
- Hence `a = 12;` has the side effect of returning the value of 12, besides assigning 12 to `a`
- Usually we don't make use of its side effect, but sometimes we do, eg:

```
z = a = 12; // or: z = (a = 12);
```

- The above makes use of the side effect of the assignment statement `a = 12;` (which returns 12) and assigns it to `z`
- Side effects have their use, but **avoid convoluted codes**:

```
a = 5 + (b = 10); // assign 10 to b, and 15 to a
```
- Side effects also apply to expressions involving other operators (eg: logical operators). We will see more of this later.

5.3 Compute (7/10)

Preprocessor
Input
Compute
Output

- Arithmetic operations
 - Binary Operators: **+**, **-**, *****, **/**, **%** (remainder)
 - Left Associative (from left to right)
 - $46 / 15 / 2 \rightarrow 3 / 2 \rightarrow 1$
 - $19 \% 7 \% 3 \rightarrow 5 \% 3 \rightarrow 2$
 - Unary operators: **+**, **-**
 - Right Associative
 - $x = - 23$ $p = +4 * 10$
 - Execution from left to right, respecting parentheses rule, and then precedence rule, and then associative rule (slide 30)
 - addition, subtraction are lower in precedence than multiplication, division, and remainder
 - Truncate result if result can't be stored (slide 31)
 - `int n; n = 9 * 0.5;` results in 4 being stored in n.

5.3 Compute (8/10)

ArithOps.c

Preprocessor
Input
Compute
Output

```
// To illustrate some arithmetic operations in C
#include <stdio.h>
int main(void) {
    int x, p, n;

    // to show left associativity
    printf("46 / 15 / 2 = %d\n", 46/15/2);
    printf("19 %% 7 %% 3 = %d\n", 19%7%3);

    // to show right associativity
    x = -23;
    p = +4 * 10;
    printf("x = %d\n", x);
    printf("p = %d\n", p);

    // to show truncation of val
    n = 9 * 0.5;
    printf("n = %d\n", n);

    return 0;
}
```

```
$ gcc ArithOps.c -o ArithOps
$ ArithOps
46 / 15 / 2 = 1
19 % 7 % 3 = 2
x = -23
p = 40
n = 4
```

5.3 Compute (9/10)

Preprocessor
Input
Compute
Output

■ Arithmetic operators: Associativity & Precedence

Operator Type	Operator	Associativity
Primary expression operators	<code>()</code> <code>expr++</code> <code>expr--</code>	Left to right
Unary operators	<code>*</code> <code>&</code> <code>+</code> <code>-</code> <code>++expr</code> <code>--expr</code> <code>(typecast)</code>	Right to left
Binary operators	<code>*</code> <code>/</code> <code>%</code>	Left to right
	<code>+</code> <code>-</code>	
Assignment operators	<code>=</code> <code>+=</code> <code>-=</code> <code>*=</code> <code>/=</code> <code>%=</code>	Right to left

Python

`expr++`, `expr--`, `++expr`, `--expr`
are not available

5.3 Compute (10/10)

Preprocessor
Input
Compute
Output

- Mixed-Type Arithmetic Operations

<code>int m = 10/4;</code>	means	<code>m = 2;</code>
<code>float p = 10/4;</code>	means	<code>p = 2.0;</code>
<code>int n = 10/4.0;</code>	means	<code>n = 2;</code>
<code>float q = 10/4.0;</code>	means	<code>q = 2.5;</code>
<code>int r = -10/4.0;</code>	means	<code>r = -2;</code> Caution!

- Type Casting

- Use a **cast operator** to change the type of an expression

- syntax: `(type) expression`

- `int aa = 6; float ff = 15.8;`

- `float pp = (float) aa / 4; means pp = 1.5;`

- `int nn = (int) ff / aa; means nn = 2;`

- `float qq = (float) (aa / 4); means qq = 1.0;`

Try out **TypeCast.c**

5.3 Compute: Difference with Python

- Python Floor Division

<code>a = 10/4</code>	means	<code>a = 2.5</code>
<code>b = 10//4</code>	means	<code>b = 2</code>
<code>c = -10/4</code>	means	<code>c = -2.5</code>
<code>d = -10//4</code>	means	<code>d = -3</code>

- Modulo

- Python % is modulo

- `a = 10%4` → `a = 2`

- `b = -10%4` → `b = 2`

- C % is remainder

- `a = 10%4` → `a = 2`

- `b = -10%4` → `b = -2`

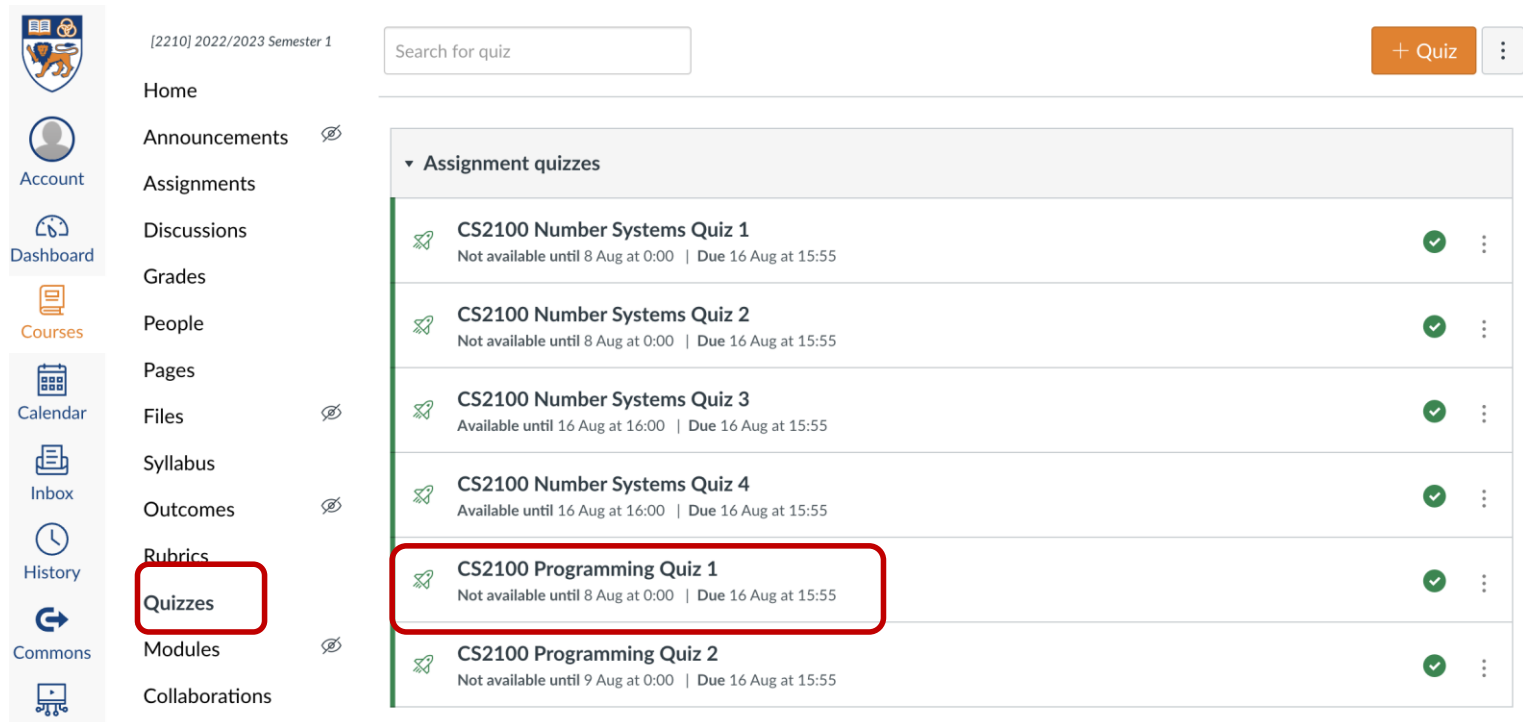

- NOTE: be careful with negative values for % operation

Try out `Modulo.c` and compare with `Modulo.py`

Quiz

- Please complete the “CS2100 C Programming Quiz 1” in Canvas.
- Access via the “Quizzes” tool in the left toolbar and select the quiz on the right side of the screen.

The screenshot displays the Canvas LMS interface. On the left sidebar, the 'Quizzes' tool is highlighted with a red box. The main content area shows a list of quizzes under the heading 'Assignment quizzes'. The quiz 'CS2100 Programming Quiz 1' is highlighted with a red box.
